

## Information Security Project 1

-Akhil Pragallapati  
-Siva Sarvana Kashyap Pathiki

Our code provided consists of a Python program for encrypting a file using symmetric-key cryptography, we have used Fernet encryption and sent the encrypted file to a remote server(another laptop in this case) using Secure Shell (SSH) protocol.

Without the key, Fernet promises that a message that has been encrypted with it cannot be altered or deciphered. Symmetric authenticated cryptography commonly referred to as "secret key" cryptography, is used by Fernet.

The program begins with Alice code by importing the necessary libraries like paramiko and randint and defining the `send_file_data` function, which we will use later to send files to the remote server(another laptop) via OpenSSH. The function takes the parameters such as `file_name`, `IP_address`, `username`, and `password` as arguments.

In this function, we first establish an SSH connection to the remote server using the `paramiko` library and the provided username and password. It then reads the contents of the specified file, uses the `SFTP` object to upload the file to the remote server (another laptop) in the specified path, and closes the connection.

Next, the program then generates a random number for Alice (`Ra_alice`) and writes it to a file named `Ra_akhil.txt`. This file is also sent to the remote server using the `send_file_data` function.

**Ra** : Alice's Random Number

Now in Bob's code, a random number for Bob(`bob_rand_int`) and writes it to a file named `bob_rand_int.txt`. This file is also sent to the remote server using the `send_file_data` function.

**Rb** : Bob's Random Number

The program generates a private key for Bob (B) and Alice (A) using the shared prime number, base, and Bob's random number. Both Alice and Bob now compute the shared secret key (KS)(shared\_secret\_key) using the Diffie-Hellman key exchange algorithm.

Now Alice's program uses the shared secret key to encrypt a file named `file_to_encrypt.txt` using Fernet encryption and writes the encrypted data to a new file named `encrypted_file.bin`. The encrypted file is then sent to the remote server using the `send_file_data` function.

Finally, Bob's program uses the shared secret key to decrypt the file named `ecrypted_file.txt` using Fernet encryption and writes the decrypted data to a new file named `decrypted_file.bin`.

Overall, this code demonstrates an implementation of symmetric-key cryptography for file encryption and Secure Shell (SSH) protocol for secure file transfer.

Scenario I:

Trudy changes the value in the encrypted file and sends the modified encrypted file to bob. Now, Bob tries to decrypt the modified encrypted file with the shared secret key and receives an error, which shows that Integrity is achieved.

The screenshot shows a Jupyter Notebook interface. At the top, the Jupyter logo is followed by the filename 'encrypted\_file.bin' and a checkmark icon, with the text 'a minute ago' to the right. Below the filename, there is a menu bar with 'File', 'Edit', 'View', and 'Language'. The main area of the notebook displays a single line of code, numbered '1' on the left margin. The code is a long alphanumeric string: `gAAAAABkD-rS6UIk-AeJgX15JFXLVkB2cRocDK8QjgQkDElXSaJiQsAHQaiJisXP_hCxGDgqJmuiH-qGyCBwPEnO_nhzjkV10DB4dsJRIjhUKRPZ3vyhpUKvyUue7CkZoDsgGcIImVgsJB8U17ewYx6aBJPLfoolwXvqycdUUS5S-ZN1bP6UKs=`

Now the changed value is:

```
1 gAAABBBkD-rS6UIk-AeJgXl5JFXLVkB2cRocDK8QjgQkDElXSaJiQsAH0QaiJisXP_hCxGDgqJmuiH-
  qGyCBwPEnO_nhzjkVl0DB4dsJRIjhUkRPZ3vyhpUKvyUue7CkZoDsgGcIImVgsJB8U17ewYx6aBJPLfoolwXvqycdUUS5S-ZN1bP6UKs=
```

After trying to decrypt the encrypted file with changed values, the program throws an error.

```
# decrypt the data
decrypted_data = f.decrypt(encrypted_data)
# write the decrypted data to a new file
with open("decrypted_file.txt", "wb") as out_file:
    out_file.write(decrypted_data)
print("File is decrypted Successfully !")

-----
InvalidSignature                                Traceback (most recent call last)
~\anaconda3\lib\site-packages\cryptography\fernet.py in _verify_signature(self, data)
    126         try:
--> 127             h.verify(data[-32:])
    128         except InvalidSignature:

~\anaconda3\lib\site-packages\cryptography\hazmat\primitives\hmac.py in verify(self, signature)
     71         ctx, self._ctx = self._ctx, None
--> 72         ctx.verify(signature)

~\anaconda3\lib\site-packages\cryptography\hazmat\backends\openssl\hmac.py in verify(self, signature)
     84         if not constant_time.bytes_eq(digest, signature):
--> 85             raise InvalidSignature("Signature did not match digest.")

InvalidSignature: Signature did not match digest.

InvalidToken                                Traceback (most recent call last)
~\AppData\Local\Temp\ipykernel_1904\3449532776.py in <module>
     26     encrypted_data = file.read()
     27     # decrypt the data
```

Scenario II:

Trudy knows  $R_a$  and  $R_b$  (random integers from Alice and Bob) from communication between Alice and Bob and tries to compute the shared secret key. As Trudy does not know the base and prime numbers, it is impossible to generate the shared secret key.

Scenario III:

Trudy performs MiM attack by replacing  $R_a$  with  $R_t$  and sends it to Bob and the replaces  $R_b$  with  $R_t$  and sends it to Alice. This will not help Trudy to generate the shared symmetric key as Trudy does not know either Bob or Alice private key which are used in creating the shared symmetric key.

Now since Trudy knows  $R_a$  and  $R_b$ , but still without the private keys of A and B respectively. Trudy can't determine the `shared_secret_key`
